Foreword

First, we would like to thank all researcher who are already send the results of scientific research papers and participated in the 5th International Symposium on Material, Mechatronics and Energy 2018. All papers in this volume has presented at ISMME 2018 by oral presentation. The papers have been peer reviewed through processes administered by the proceedings Editors. Reviews were conducted by expert referees to the professional and scientific standards expected of a proceedings journal published by IOP Publishing.

Our theme is Challenges and Opportunities of Materials Engineering, Mechatronics and Energy towards independence of independent and sustainable technology products. Themes have been given an important role of Indonesian Development of Industrial Manufacture strategic plan, where the Indonesian people are still in desperate need of technology in these areas, material, mechatronics and energy.

Today Issues is still on Industry 4.0, they are five items should be considered:
1. Scalability; The automation principle of Industry 4.0 could help to facilitate improved scalability among companies in the manufacturing sector.
2. Security; One of the foremost concerns about Industry 4.0 among manufacturers is the possibility of mishaps due to glitches in cognitive computing.
3. Control and Visibility; As manufacturing networks globalize, it is crucial to make digital processes visible to all points of a system. When fully implemented, the principles of Industry 4.0 support responsiveness by making information available worldwide within a fraction of a second.
4. Customer Satisfaction; The process will be fully transparent along all stops on the manufacturing chain, from the moment someone places an order or submits a design until the moment when shipments arrive. Industry 4.0 will facilitate co-creation capabilities between manufacturers and related entities on a global scale.
5. Customization; Industry 4.0 could take customization to new levels with the use of commercial 3-D printers, which there are 23,000 of in use worldwide.

We hope many researchers play on such conditions. Finally, thanks to all of my college in Faculty of Engineering Hasanuddin University, Okayama University, Graduate School of Unhas, Research and Community Services Institute of Unhas and Polytechnik State of Ujung Pandang.

Makassar-Gowa, November , 2018
Yours

Dr. Ir. Muhammad Arsyad Thaha, MT
Dean of Engineering Faculty of Hasanuddin University
Peer Review Statement

All papers published in this volume of Journal of Physics: Conference Series have been peer reviewed through processes administered by the proceedings Editors. Reviews were conducted by expert referees to the professional and scientific standards expected of a proceedings journal published by IOP Publishing.

Abstract. The purpose of this research is to determine the tensile stress and interfacial shear stress of coconut fiber that has been treated Sodium Hydroxide and Potassium Permanganate. This research is divided into three stages: soaking for 3 hours, testing, and data analysis. Coconut fiber is soaked in a solution of 5%, 10%, 15%, and 20% sodium hydroxide solution. Then, soaking in a solution of Potassium Permanganate with concentrations of 0.25%, 0.50%, 0.75%, and 1.00%. After that, the coconut fiber is dried in the furnace at 90°C for 5 hours. Then, coconut fiber was tested for tensile stress and interfacial shear stress. Based on the results of the test can be concluded that the treatment of Sodium Hydroxide and Potassium Permanganate affect tensile strength, and the shear strength of coconut fiber. The largest tensile stress was obtained in the treatment of Sodium Hydroxide with a concentration of 20% ie 289.94 N/mm², while the highest interfacial shear stress was obtained in the treatment also on Sodium Hydroxide with a concentration of 20% ie 3.09 N/mm².

Keywords. treatment, tensile, shear, stress, coir fiber.

1. Introduction
Lignocellulose is the name used for materials containing lignin, cellulose, and hemicellulose. Lignocellulose is a constituent component of plant cell wall especially on the stem section. Hemicellulose and cellulose are polysaccharides that can be decomposed into monosaccharides. The availability of abundant lignocellulosic materials on earth has resulted in the study of the use of lignocellulosic materials to be very attractive[1].

Natural fibers containing hemicellulose, cellulose, and lignin are hydrophilic which is a feature that likes to water. It is this property that causes natural fibers to hardly unite or bind with a hydrophobic matrix of a dislike of water. Therefore, there is a need to improve the properties of the natural fibers in order to establish a good bond with the matrix. Treatment of lignocellulosic materials can be done in several ways as chemically, physically, and microbiologically. Each method has advantages and disadvantages. The efficiency and effectiveness of its use may vary, depending on the source of the material and the purpose of the process. Chemical treatment is the most commonly used method because it is easier, more effective, faster and does not use too high energy. The bond between fiber and matrix has an effect on the mechanical properties of fiber-reinforced composites. Specifically, the composite tensile strength is affected by the efficiency of the load transfer from the matrix to the fiber through shear at the interface. Therefore, a number of mechanical tests have been
developed to measure the interface capacity to transfer the stress from the matrix to the fibers in the composite. Several test methods have been used to evaluate the bond capability between fibers and matrices such as: (1) pull outs, (2) microtension, (3) microcompression, (4) fragmentation. The interconnection of the fiber with the matrix consists of several bond models: (a) chemical bonds, (b) ionic electrostatic bonds, (c) molecular reaction interdiffusion, and (d) mechanical bonds (interlocking) [2].

The composite mechanical properties are strongly influenced by the bond between the matrix and the fibers. Treatment with sodium hydroxide has the highest effect on tensile strength and tensile modulus, resulting in composites with the best tensile properties. The strength of the composites treated with sodium hydroxide increased significantly by about 53% compared to composites made from untreated fibers and 33% compared to the non-fiber composite [3]. The alkali treatment of the fibers will give two effects to the fibers: (1) increasing the surface roughness of the fibers so as to produce better interlocking, (2) increasing the release of cellulose [4]. The reaction between fiber and sodium hydroxide are [1] [5]:

$$\text{Serat-OH} + \text{NaOH} \rightarrow \text{Serat-O-Na + H}_2\text{O}$$

Permanganate is a compound containing MnO4- permanganate groups. Permanganate strengthening is used on cellulose fibers that turn into radicals through the formation of permanganate ions. Then the highly reactive Mn3+ ion as the initiation of the graph copolymerization [6] [8].

Most permanganate strengthening is carried out by using a solution of potassium permanganate (KMnO4) or in acetone with different concentrations within 1 to 3 hours after alkaline strengthening, strengthening the hemp fiber in permangant solution at a concentration of 0.033: 0.0626: and 0.125% in acetone for one minute. As a result of permanganate strengthening is a reduction in the fiber, therefore the water absorption of fiber-reinforced composites increases. The hydrophilic properties of the fibers will decrease with the increase of KMNO4 concentration, but at 1% KMnO4 concentration there is cellulose degradation which will produce polar groups between the fibers and the matrix [6].

### 2. Material and Methods

The materials used in this research are: coconut fiber, polyester resin, metyl etyl keton peroksida catalyst, sodium hydroxide (NaOH), potassium permanganate (KMnO4), and aquades. The equipments used in this study are digital scales, immersion media, manila cartons, glue, scissors, tensile test equipment. Coconut fiber is obtained from coconut husk with manuually method. Coconut fiber is soaked in sodium hydroxide solution for 3 hours with concentrations of 5%, 10%, 15%, and 20%. Then soaked also for 3 hours in solution 0.25%, 0.5%, 0.7.5%, and 1.00%. Subsequently, coconut fiber was dried in a furnace at 90°C for 5 hours.

The stress occurring at a maximum limit indicates a load capable of being retained by a material called the maximum stress. The maximum stress held by the specimen before break is called the maximum tensile stress that is the ratio between the maximum load and the cross-sectional area of the material. Single fiber tensile specimens were prepared according to ASTM 3379-02 Standard as shown in Fig. 1, whereas the shearing mechanism between fiber and matrix is shown in Fig. 2. The maximum tensile stress value is calculated by using equation 1, while the shear stress value between the fibers and the matrix is calculated using equation 2. The single tensile fiber and pull out test is performed by using the LR10K Plus 10 kN Universal Materials Testing Machine.

Figure 3. Tensile stress value of coconut fiber
Figure 4. Strain value of coconut fiber

Table 2 and Fig. 3 show that the highest tensile stress is obtained on coconut fiber treatment with 20% alkali which is 280.94 MPa, and this value is higher than coco fiber without treatment ie 186.42 MPa. This indicate that the alkali treatment of coconut fiber can increase the tensile strength of coconut fiber [3][4][6]. In this treatment coconut fiber contains the lowest lignin that is only 6.1%. This value is lower than the lignin content of coconut fiber without treatment ie 33.5% as shown in table 4 and fig 6. This represent that the alkali treatment of coconut fiber results in lignin degradation so that influence the tensile strength of coconut fiber [7]. While the highest strain of coconut fiber is obtained at 5% alkali treatment which is 50% as shown in fig 4. In this treatment, coconut fiber contains the lowest hemisellulose that is 11% lower than coconut fiber without treatment ie 15.5%. This shows that alkaline treatment degrades the number of coconut fiber hemisellulose [6].

The results of pull out test are shown in Table 3 and figure 5.

Table 3 and Fig 5 shows the shear stress of coconut fiber, both of which have been treated or untreated. The highest shear stress is found in coconut fiber treated with alkali 20% that is 3.09 MPa. The shear stress value is higher than the value of the shear stress without treatment coconut fiber is 1.85 MPa. This indicate that the alkali treatment of coconut fiber has compatibility to polyester matrix. While on the other treatment obtained at the treatment of alkali 10% and potassium permanganate 0.50% that is equal to 2.82 MPa. Overall, potassium permanganate treatment after alkali treatment increased the shear stress of coco fiber with a polyester matrix except at 1% potassium permanganate treatment after 20% alkali treatment, the shear stress decreased from 2.09 MPa to 1.19 MPa. The treatment of potassium permanganate caused a reduction in the amount of cellulose, the highest amount of cellulose obtained in coconut fiber without treatment ie 37.9% while the lowest amount of cellulose was obtained in potassium permanganate treatment with 0.75% concentration of 21.6% [6,9].

4. Conclusion
Based on the testing and discussion that has been done then concluded:

a. The tensile stress of coconut fiber is increased by sodium hydroxide treatment but decreases in potassium permanganate treatment.

b. The treatment of sodium hydroxide, and potassium permanganate increases the compatibility between coconut fiber and polyester matrix.
